PUBLIC UTILITIES COMMISSION

The Honorable Chairman and Members of the
Hawaii Public Utilities Commission
465 South King Street
Kekuanaoa Building, 1st Floor
Honolulu, Hawaii 96813

Dear Commissioners:

Subject: Docket No. 2006-0387
MECO 2007 Test Year Rate Case
Calibration Factor Annual Report for Year 2007

In accordance with the Stipulated Settlement Letter executed by MECO and the Division of Consumer Advocacy of the Department of Commerce and Consumer Affairs (the "Consumer Advocate") (collectively referred to as the "Parties") in this proceeding enclosed for filing is Maui Electric Company, Limited's ("MECO") annual calibration factor report for year 2007. The Stipulated Settlement Letter filed with the Commission on December 7, 2007, specifically states in paragraph 7: "MECO agrees to file annual reports on its calibration factor."

Please call Dean Matsuura at 543-4622 if you have any questions regarding the enclosed report.

Sincerely,

Edward L. Reinhardt

Enclosure

cc: Division of Consumer Advocacy
Peter Y. Kikuta, Esq.
Thomas W. Williams, Jr., Esq.

Maui Electric Company, Limited
Annual Calibration Factor Report for Year 2007
March 14, 2008

1.0 Introduction

This document provides to the Hawaii Public Utilities Commission ("Commission") and the Division of Consumer Advocacy of the Department of Commerce and Consumer Affairs ("Consumer Advocate") the calibration factors for year 2007 in accordance with the Commission's Interim Decision & Order No. 23926 (filed December 21, 2007) and the stipulated settlement agreement in Docket No. 2006-0387, Maui Electric Company, Limited ("MECO") Test Year 2007 Rate Case. The calibration factor applies only to the Maui Division, as the Molokai and Lanai Divisions did not use production simulations in Docket No. 2006-0387 to determine system fuel consumption. Rather, system fuel consumption for the Molokai and Lanai Divisions was determined by using the estimated test year system heat rate derived from the average system heat rate over the five-year (2001-2005) period multiplied by the test year generation required to serve the load..

As discussed further below, the calibration factors for year 2007, based on recorded January through December 2007 data, are 1.023 system-wide, 1.039 for industrial fuel oil, and 1.026 for diesel fuel. The calibration factors previously calculated for use in MECO's Test Year 2007 Rate Case for year 2005 was 1.017 for industrial fuel oil, and 1.016 for diesel.

2.0 Background

2.1 Calibration Factor

The purpose of a calibration factor in the context of a rate case is to adjust the fuel consumption determined by a computer production simulation to account for actual operating conditions that are not accurately simulated by the computer model. The calibration factor is a constant number that can be greater than, equal to, or less than 1.00. The test year fuel consumption (in Btus) determined by the production simulation is multiplied by this factor.

2.2 Calibration Factor Issue

In HELCO's Test Year 2000 rate case, Docket No. 99-0207, HELCO used a revised calibration factor of 1.027 based on a calibration to 1999 actual production statistics. The calibration factor is a necessary adjustment to the results of the production simulation model to reflect the actual operation of the generating units in the real world. The Consumer Advocate opposed the use of a calibration factor. HELCO's position is set forth in its Opening Brief filed October 25, 2000 (pages 122-127) and

Reply Brief filed December 4, 2000 (pages 75-77) in Docket No. 99-0207, and the Consumer Advocate's position is set forth in its Opening Brief filed October 25, 2000 (pages 101-105) and Reply Brief filed December 4, 2000 (pages 40-43) in Docket No. 99-0207.

In its Decision & Order ("D&O") No. 18365, issued on February 8, 2001, on pages 18-19, in Docket No. 99-0207, the Commission ordered HELCO to file annual reports on HELCO's calibration factor.

2.3 Stipulated Settlement Letter for MECO Rate Case

In MECO's Test Year 2007 Rate Case in Docket No. 2006-0387, the Consumer Advocate stated in CA-T-2, page 20, "...I recommend that the Commission continue to require MECO, and the other utilities under its jurisdiction, to provide annual calibration reports."

In a Stipulated Settlement Letter from MECO and the Consumer Advocate (collectively referred to as the "Parties") submitted to the Commission on December 7, 2007, in Docket No. 2006-0387, the Parties agreed that MECO will file annual reports on MECO's calibration factor. As stated on pages 6 and 7 of the Stipulated Settlement Letter, "The Consumer Advocate recommended, however, that MECO continue to be required to provide annual calibration reports to allow the Commission and Consumer Advocate an opportunity to monitor the difference between the estimated and actual results produced from the use of the production simulation model. MECO agrees to file annual reports on its calibration factor".

This report is being filed in accordance with the Parties' Stipulated Settlement Letter and covers the 2007 calibration year.

3.0 Determination of the Calibration Factor - Analytical Methodology

A calibration factor is determined by using a computer model to simulate the operation of the utility production system for a recorded year, called the "calibration year," and determining the ratio between the computer model outputs and recorded amounts for the calibration year.

3.1 Production Simulation

MECO uses a computer model, called P-MONTH, supplied by the P Plus Corporation ("PPC"), to perform the production simulation. This model simulates the chronological, hour-by-hour operation of MECO's generation system by dispatching (i.e., mathematically allocating) the forecasted hourly kilowatt load among the available generating units.

Generating units in the model are represented as thermal units and fixed and hourly purchased energy transactions. An output report produced by the production simulation model lists the fuel consumption in MBtus and the energy in GWh of each thermal unit by month.

3.1.1 Thermal units

The units modeled as thermal units in P-MONTH are all MECO-owned generators at the Kahului and Maalaea generating stations. Unit commitment for these thermal units were based on a typical MECO unit commitment order. Dispatch levels for these thermal units are based on how MECO dispatched the units from their Automatic Generation Control ("AGC") system, direct operator control, and the desire to equalize operating hours to maximize maintenance cycle efficiency. The model calculates the fuel consumed using the unit dispatch described above, based on the load carried by the unit and the unit's efficiency characteristics. The total fuel consumed hourly by the MECO system is the summation of each unit's hourly fuel consumption.

MECO also owns two emergency diesel generating units at the Hana Substation. These units are represented in P-MONTH as a fixed energy transaction due to their limited and infrequent use. Therefore, they are not included with the daily commitment and dispatch of other MECO generating units. The generation from the Hana Distributed Generation ("DG") units reduces the load that must be served by the central station and IPP generating units.

3.1.2 Fixed Energy Transactions

MECO has an existing power purchase contract with Hawaiian Commerical & Sugar Company ("HC&S") to purchase up to 16 MW of firm generating capacity. This purchased power is represented in P-MONTH as a fixed energy transaction. In addition, MECO purchases as-available generation from two Independent Power Producers, Kaheawa Wind Power, LLC ("KWP") and Makila Hydro LLC, ("Makila"). These as-available power producers, consisting of a wind farm and a run-of-river hydro unit, respectively, are represented in the P-MONTH model as hourly purchase energy transactions. An energy transaction acts as a load modifier, which means that the load levels are reduced by the amount of energy that is produced and supplied by the generating facility to the utility. The energy reduces the load levels before the utility thermal units are dispatched. Each transaction is represented by an average load level and actual MWh generated for each month. The average load level in each hour for each as-available unit is subtracted from the hourly system load profile in the model.

Wind farms and hydro units do not use fuel cost inputs and are not included in the total fuel consumption for the MECO system; therefore, they are not included in the calculation of the calibration factors.

3.1.3 Simulation Options

P-MONTH has two simulation options: (1) probabilistic, and (2) Monte Carlo. For reasons put forward and explained in MECO's Test Year 2007 Rate Case, Docket No. 2006-0387, MECO T-4, page 33, line 15, to page 34, line 4, it was determined that the Monte Carlo technique is better able to simulate the actual operation of the system in the calibration year. Based on this evaluation, MECO used the Monte Carlo option in determining the calibration factor for this report.

3.1.4 Calibration by Fuel Type

In addition to adopting the Monte Carlo option for this report, MECO also examined the ability of the model to capture the operation of the generating units by the two fuel types used by MECO – Industrial Fuel Oil ("IFO") and diesel fuel. In 2007, approximately 26% of MECO's generation was provided by the use of IFO and 74% by diesel fuel. In the previous MECO test year rate case (1999), the calibration factor was reduced to a single system-wide value.

For reasons put forward and explained in MECO's Test Year 2007 Rate Case, Docket No. 2006-0387, MECO T-4, page 33, lines 7-14, two calibration factors are being used, one for each fuel type.

3.2 Calibration Factor Calculation

The production simulation results for the calibration year are compared to the actual recorded data for the calibration year and a calibration factor is derived using actual and simulated fuel consumption, energy generated and unit heat rates. The following sections provide an explanation of how the actual and simulated, fuel consumption, energy generation and unit heat rates are used when calculating the calibration factor. Actual data are taken from MECO production reports, which are shown in Appendix A, Page 62. Simulated data are taken from P-MONTH monthly and yearly output reports which are a result of the production simulation.

3.2.1 Fuel Consumption

Actual fuel consumption for each unit is recorded on MECO production reports in barrels of diesel fuel and IFO consumed by MECO generating units. The actual amount of diesel fuel consumed is converted to MBtus

by multiplying the barrels consumed by the average MBtu content of 5.86 MBtu/barrel.[1] The actual amount of industrial fuel consumed is converted to MBtus by multiplying the barrels consumed by the average MBtu content of 6.3 MBtu/barrel.[2] The actual amount of fuel consumed by MECO units in MBtus is the sum of the diesel fuel consumed and the IFO consumed and is used in calculating the actual system-wide heat rate explained in section 3.2.3.

The yearly report from P-MONTH production simulation displays the simulated fuel, in MBtus, consumed by each unit. The simulated amount of fuel consumed by MECO units is calculated by summing the MBtus consumed by all MECO-owned fossil-fuel units and is used in the calculation of the system-wide calibration factor. This is explained in more detail in section 3.2.4.

3.2.2 Energy

The actual net energy in kWh generated by each unit is recorded on MECO production reports. The calibration factor calculation uses the total net kWh (converted into MWh) generated by MECO-owned units not including the Kaheawa Wind Farm, Makila Hydro generating units, the HC&S generating units, and the DG units at the Hana substation. An explanation of how the calibration factor calculation uses the total net energy generated by the MECO-owned units is provided in section 3.2.3.

The yearly report from the P-MONTH production simulation lists the total net GWh generated by each unit for the calibration year. The simulated net energy generated is calculated by summing the GWh generated by all MECO-owned units not including the Kaheawa Wind Farm, the Makila units, the HC&S units, and the DG units at the Hana substation. The GWh are converted into MWh for the calibration factor calculation. An explanation of how the calibration factor calculation uses the simulated net energy generated by the MECO-owned units is explained in section 3.2.4.

---

[1] Average MBtu content of 5.86 MBtu/bbl for diesel fuel is specified in the fuel delivery contracts with Chevron and Tesoro (MECO's two fuel suppliers). Fuel testing for MBtu content is done for each delivery to insure specifications are adhered to by the fuel supplier.

[2] Average MBtu content of 6.3 MBtu/bbl for industrial fuel is specified in the fuel delivery contracts with Chevron and Tesoro (MECO's two fuel suppliers). Fuel testing for MBtu content is done for each delivery to insure specifications are adhered to by the fuel supplier.

3.2.3 Heat Rate

For the calibration factor calculation, the actual net heat rate using recorded values from the calibration year is calculated. The net heat rate, in MBtu/MWh, is the fuel consumption divided by the total net energy and is used in calculating the calibration factor.

3.2.4 Calibration Factor

The calibration factor is the ratio between the actual heat rate and the simulated heat rate from the P-MONTH model for the calibration year. The simulated fuel consumption in MBtus from the production simulation (derived in section 3.2.1) is divided by the simulated net energy generated by the MECO-owned units from the production simulation (derived in section 3.2.2) to obtain the simulated heat rate. The actual heat rate is then divided by the simulated heat rate from the production simulation to obtain the calibration factor.

4.0 Results for Year 2007

The calibration factors for year 2007, based on recorded January through December 2007 data, are 1.023 system-wide, 1.039 for IFO generation and 1.026 for diesel fuel generation. The system-wide calibration factor used in MECO's Test Year 1999 Rate Case for year 1996, was 0.992. The calibration factors used in MECO's Test Year 2007 Rate Case (Calibration Factors for Year 2005) were 1.016 system-wide, 1.017 for industrial fuel oil, and 1.016 for diesel fuel. The worksheet showing the calculation of the 2007 factor is shown in Table A-1 of Appendix A.

4.1 Specific Assumptions

The key inputs to the production simulation model, when applied to the MECO system, are as follows:

- energy and hourly load to be served by the MECO system,
- energy and hourly load to be served by firm and non-firm purchased power producers,
- load carrying capability of each MECO and firm power producer generating unit,
- efficiency characteristics of each MECO and firm power producer generating unit,
- calculated penalty factors used to commit MECO units,
- operating constraints such as must-run units or minimum energy purchases from purchased power producers,
- actual planned maintenance outages for the generating units,

- estimated forced and unplanned maintenance outages for the generating units, and
- inventory prices for fuels used by the generating units.

4.2 Differences between 2007 Modeled and Actual Results

The results from the production simulation were compared to the actual recorded energy and run time for the system. The net energy and run time comparisons are shown in Figures A-1 and A-2 of the Appendix, respectively. The largest deviations between the production simulation and actual results were in the cycling and peaking units. The noticeable differences include, but are not limited to, the following:

- The actual net energy for the two dual-train combined cycle units is higher than in the production simulation;
- The actual net energy for Maalaea Units M12 and M13 was lower than in the production simulation;
- The actual net energy for Kahului Units 3 and 4 was lower than in the production simulation;
- The actual net energy and run time for the Maalaea 8 and 9 diesels was lower than in the production simulation; and
- The actual net energy and run time for the Maalaea peaking units was higher than in the production simulation.

4.3 Reasons for Differences in 2007 Modeled and Actual Results

The actual operating conditions of the utility system are simulated in the computer model as accurately as possible; however, there are some operating conditions that cannot be accurately simulated in the model. Whenever there is a difference between actual and modeled operation, there will likely be a difference between actual and modeled production statistics. The operating conditions that cannot be accurately simulated by the computer model include, but are not limited to, those identified in MECO's Direct Testimony, T-4, page 31-35, in Docket No. 2006-0387. In summary, these include:

- temporary unit deratings
- changes in unit commitment order
- unpredictable nature of intermittent, as-available resources
- actual system conditions
- changes in penalty factors updated every 15-minutes
- actual system load
- steam turbine and combustion turbine performance

4.3.1 Temporary Unit Deratings

Not all actual unit deratings that occurred in the calibration year are reflected in the production simulation. Deratings are not reflected in the model unless they are sustained for the majority of the month. If a unit is derated at various levels during a month, the average MW level of the derating is used in the production simulation. For example, HC&S's actual MW level was not constant at 12 MW for all on-peak hours and 8 MW for all off-peak hours in 2007. HC&S was modeled using their average MW level for each month.

4.3.2 Changes in Unit Commitment Order

Not all changes in unit commitment that occurred in the calibration year can be reflected in the production simulation. There are several reasons why changes in unit commitment order occurred in 2007. These reasons include, but are not limited to, the following:

a. A unit which has a problem with a piece of auxiliary equipment, such as a tube leak, may be placed at the bottom of the commitment order to reduce the risk of failure;

b. Operational constraints on the system requiring generation to be operated differently to avoid transmission component overload or provide voltage support and/or reduce risk conditions during poor weather or other dynamic situations such as the behavior of as-available energy production;

c. Planned or unplanned outage of a generating unit low in the commitment order; including independent power producers, can alter the remaining commitment order even to the point of making an intermediate unit operate as a baseload unit.

Steps are taken to minimize differences between actual and modeled operations attributable to the unit commitment order. In instances where it is known that actual operations deviate from the typical commitment order due to operational reasons, an adjustment is made in the modeling.

4.3.3 Actual System Conditions

There were many unpredictable events that occurred in 2007 that the production simulation could not accurately simulate. These events include, but are not limited to, the following

a. With the installation of the Maalaea Unit 18 in October 2006 to complete the dual train combined cycle unit, MECO in 2007 conducted performance tests and performed procedures to optimize the operation of the unit which affected the operation of not only the dual train combined cycle unit, but also the other MECO units.

b. Hourly pattern files are used in the production simulation to capture operating restrictions on the generating units. For example, Kahului Units 1 and 2 are usually available during the hours of 5:00 am and 9:00 pm, but both units operate as baseloaded units when either of the Kahului units 3 or 4 are on scheduled maintenance.

c. The planned outage schedules for all the MECO thermal units are input in the computer model. Unplanned maintenance outages are incorporated into the computer model as a percentage of time over the entire year. The P-MONTH computer model has the capability of automatically scheduling unplanned maintenance outages for all the thermal units based on the maintenance outage rate ("MOR"). However, the MOR is rounded to the nearest week and scheduled as one block of time. For example, an MOR of 1.11% is equivalent to 4 days, but the computer model will round this to 1 week or 7 days.

   For future production simulations, the automatic maintenance scheduling model would be used along with a historical MOR to account for future unplanned outages. Therefore, the methodology used to account for unplanned scheduled outages in the calibration year is consistent with the methodology that would be used for a forward-looking year.

d. Actual forced outage events, partial and full outages, are incorporated into the computer model using the FOR percentage over the entire year. Therefore, the modeled forced outages may not occur at the same times or for the same durations as the actual outages. This will result in some differences in unit dispatch between modeled and actual results. For large forced outage events, the actual outage was input into the model and the FOR percentage was recalculated to reflect this modification.

e. The production simulation includes an amount of regulating reserve, as identified in MECO's Test Year 2007 Rate Case, Docket No. 2006-0387, MECO T-4, page 27. Under normal operating conditions, MECO carries about a 15 MW regulating reserve. As stated in MECO's Test Year 2007 Rate Case, MECO T-5, page 8, "...MECO decided to use 8 MW as an average level of regulating reserve required to cover KWP. The 8 MW plus the 7 MW of base

regulating reserve results in 15 MW of total regulating reserve. In reality, there may have been instances when there was more or less reserve at any given hour than what was captured in the model. During times of high as-available (wind) production, MECO may maintain a larger amount of reserve, up to the amount of as-available energy production in order to maintain reliable service to customers as wind power output fluctuates.

f. As-available energy from wind and hydro units in actuality can vary from minute-to-minute, hour-to-hour, and day-to-day. As described in section 3.1.2, as-available energy from wind is treated as an hourly transaction in the model, so the variability by minute, is not captured by the production simulation. Although the as-available energy is not included in the calculation of the calibration factor itself, it does impact the generation of the firm units which are used to calculate the calibration factor.

g. In 2007, MECO performed biodiesel fuel testing at the Maalaea Generating Station. At least one of each type of diesel-fired generating unit (i.e., combustion turbine, Mitsubishi diesel engine, EMD, Cooper-Bessemer, Colt-Pielstick) was tested to determine fuel efficiency and emission rates at various loads when using biodiesel. Each test was conducted for a relatively short period of time under controlled conditions. The production simulation model does not have the resolution to capture the precise performance of the generating units during the testing.

5.0 Observation

Differences in system operating conditions affect the calibration factor from year to year. One of the major differences between 2005 and 2007 was the addition of the as-available wind energy from the KWP facility. The KWP facility began operations in June 2006. Therefore, in 2005, the MECO system was unaffected by the KWP facility. However, in 2006, the MECO system realized impacts for only half of the year, whereas, in 2007, KWP provided energy for the entire year.

In addition, on December 9, 2005, Maalaea Unit 13, a 12.34 MW (net) Mitsubishi diesel engine generator, suffered equipment failure causing extensive damage and was not able to operate for all of 2006 and parts of 2005 and 2007. Repairs to M13 were completed and the unit was returned to operation on July 9, 2007.

On October 27, 2006, Maalaea Unit 18, a nominal 17.1 MW (net) steam turbine generator, was placed into commercial operation. Maalaea Unit 18 is the third and final phase of a Dual Train Combined Cycle system that consists of two combustion turbines and the steam turbine generator totaling 56,78 MW (net). Due to the addition of the KWP facility, the damage and repairs to Maalaea Unit 13, and the addition of Maalaea Unit 18, there was a change in system generation mix, as well as the changes in system demand profile and actual net energy calculation methodology. This contributed to the differences in the calibration factors from 2005 to 2007.

The larger calibration factor derived for 2007 can be attributed in large part to the unpredictable nature of the wind power output, which varies from second to second. The production simulation model does not have the capability to capture or simulate this random variability or the generating units' actions to compensate for the wind power fluctuations.
